

Overview of Time Series and Forecasting:

Data taken over time (usually equally spaced)

Y_t = data at time t μ = mean (constant over time)

Models:

“Autoregressive”

$$(Y_t - \mu) = \alpha_1(Y_{t-1} - \mu) + \alpha_2(Y_{t-2} - \mu) + \dots \\ + \alpha_p(Y_{t-p} - \mu) + e_t$$

e_t independent, constant variance: “White Noise”

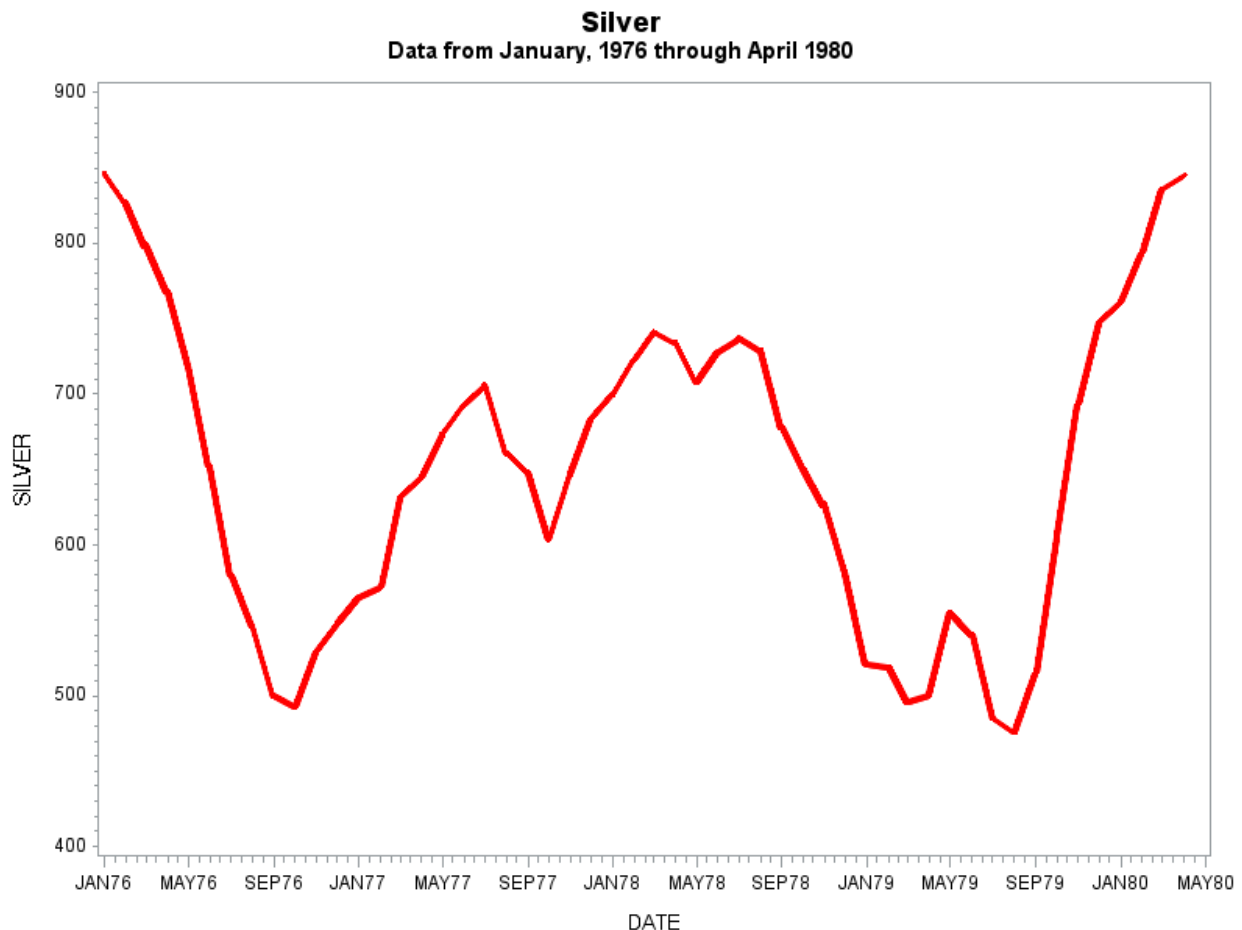

How to find p ? Regress Y on lags.

PACF Partial Autocorrelation Function

(1) Regress Y_t on Y_{t-1} then Y_t on Y_{t-1} and Y_{t-2}
then Y_t on $Y_{t-1}, Y_{t-2}, Y_{t-3}$ etc.

(2) Plot **last lag coefficients** versus lags.

Example 1: Supplies of Silver in NY commodities exchange:

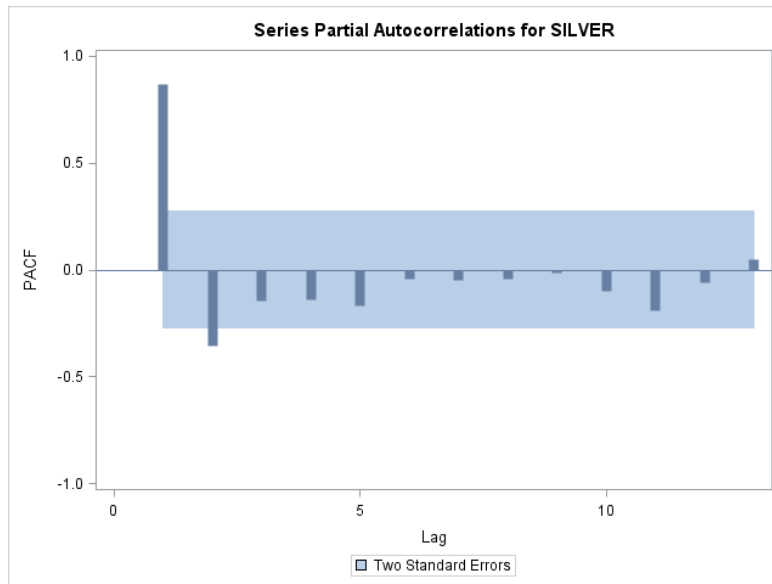

Getting PACF (and other identifying plots). SASTM code:

```
PROC ARIMA data=silver  
  plots(unpack) = all;  
  identify var=silver; run;
```

TM SAS and its products are registered trademarks of SAS Institute, Cary NC.

PACF

“Spikes” outside 2 standard error bands are statistically significant

Two spikes $\rightarrow p=2$

$$(Y_t - \mu) = \alpha_1(Y_{t-1} - \mu) + \alpha_2(Y_{t-2} - \mu) + e_t$$

How to estimate μ and α 's ? PROC ARIMA's ESTIMATE statement.

Use maximum likelihood (ml option)

```
PROC ARIMA data=silver plots(unpack) = all;  
  identify var=silver;
```

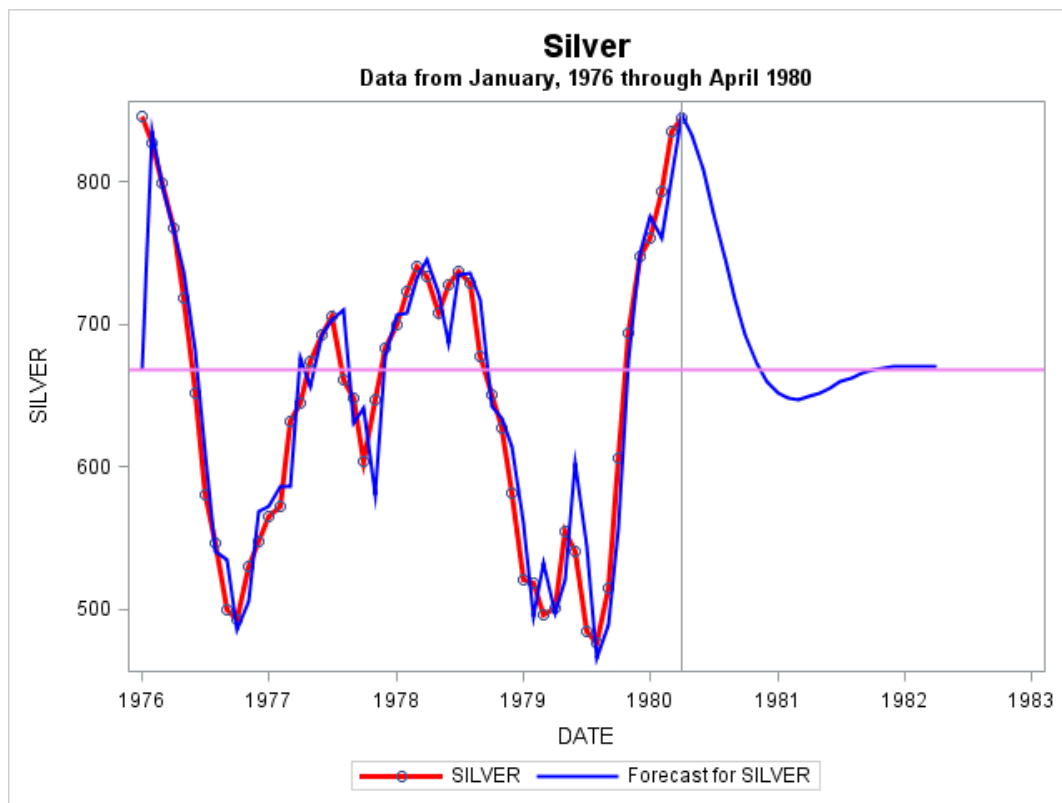

```
  estimate p=2 ml;
```

| Maximum Likelihood Estimation | | | | | |
|-------------------------------|-----------|----------------|---------|----------------|-----|
| Parameter | Estimate | Standard Error | t Value | Approx Pr > t | Lag |
| MU | 668.29592 | 38.07935 | 17.55 | <.0001 | 0 |
| AR1,1 | 1.57436 | 0.10186 | 15.46 | <.0001 | 1 |
| AR1,2 | -0.67483 | 0.10422 | -6.48 | <.0001 | 2 |

$$(Y_t - \mu) - \alpha_1(Y_{t-1} - \mu) - \alpha_2(Y_{t-2} - \mu) = e_t$$

$$(Y_t - 668) - 1.57(Y_{t-1} - 668) + 0.67(Y_{t-2} - 668) = e_t$$

$$(Y_t - 668) = 1.57(Y_{t-1} - 668) - 0.67(Y_{t-2} - 668) + e_t$$

Backshift notation: $B(Y_t) = Y_{t-1}$, $B^2(Y_t) = B(B(Y_t)) = Y_{t-2}$
 $(1 - 1.57B + 0.67B^2)(Y_t - 668) = e_t$

SAS output: (uses backshift)

| |
|--|
| <p style="text-align: center;">Autoregressive Factors</p> <p>Factor 1: 1 - 1.57436 B**(1) + 0.67483 B**(2)</p> |
|--|

Checks:

(1) Overfit (try AR(3))

| Maximum Likelihood Estimation | | | | | | |
|-------------------------------|-----------|----------------|---------|-------------------|----------|--|

| AR1,3 | -0.07883 | 0.14376 | -0.55 | 0.5834 | 3 | |

(2) Residual autocorrelations

Residual r_t

Residual autocorrelation at lag j : $\text{Corr}(r_t, r_{t-j}) = \rho(j)$

Estimate, square, and sum k of these multiply by sample size n. PROC ARIMA: k in sets of 6. Box-Pierce Q statistic. Limit distribution Chi-square if errors independent. Later modification: Box-Ljung statistic for H_0 :residuals uncorrelated

$$n \sum_{j=1}^k \left(\frac{n+2}{n-j} \right) \hat{\rho}_j^2$$

SAS output:

| Autocorrelation Check of Residuals | | | | | | | | | |
|------------------------------------|----------------|----|---------------|------------------|--------|--------|--------|--------|--------|
| To Lag | Chi- Square | DF | Pr > ChiSq | Autocorrelations | | | | | |
| 6 | 3.49 | 4 | 0.4794 | -0.070 | -0.049 | -0.080 | 0.100 | -0.112 | 0.151 |
| 12 | 5.97 | 10 | 0.8178 | 0.026 | -0.111 | -0.094 | -0.057 | 0.006 | -0.110 |
| 18 | 10.27 | 16 | 0.8522 | -0.037 | -0.105 | 0.128 | -0.051 | 0.032 | -0.150 |
| 24 | 16.00 | 22 | 0.8161 | -0.110 | 0.066 | -0.039 | 0.057 | 0.200 | -0.014 |

Residuals uncorrelated \leftrightarrow Residuals are White Noise
 \leftrightarrow Residuals are unpredictable

SAS computes Box-Ljung on original data too.

| Autocorrelation Check for White Noise | | | | | | | | | |
|---------------------------------------|----------------|----|---------------|------------------|--------|--------|--------|--------|--------|
| To Lag | Chi- Square | DF | Pr > ChiSq | Autocorrelations | | | | | |
| 6 | 81.84 | 6 | <.0001 | 0.867 | 0.663 | 0.439 | 0.214 | -0.005 | -0.184 |
| 12 | 142.96 | 12 | <.0001 | -0.314 | -0.392 | -0.417 | -0.413 | -0.410 | -0.393 |

Data autocorrelated \leftrightarrow predictable!

Note: All p-values are based on an assumption called “stationarity” discussed later.

How to predict?

$$(Y_t - \mu) - \alpha_1(Y_{t-1} - \mu) - \alpha_2(Y_{t-2} - \mu) = e_t$$

One step prediction

$$\hat{Y}_{t+1} = \mu + \alpha_1(Y_t - \mu) + \alpha_2(Y_{t-1} - \mu), \text{ future error} = e_{t+1}$$

Two step prediction

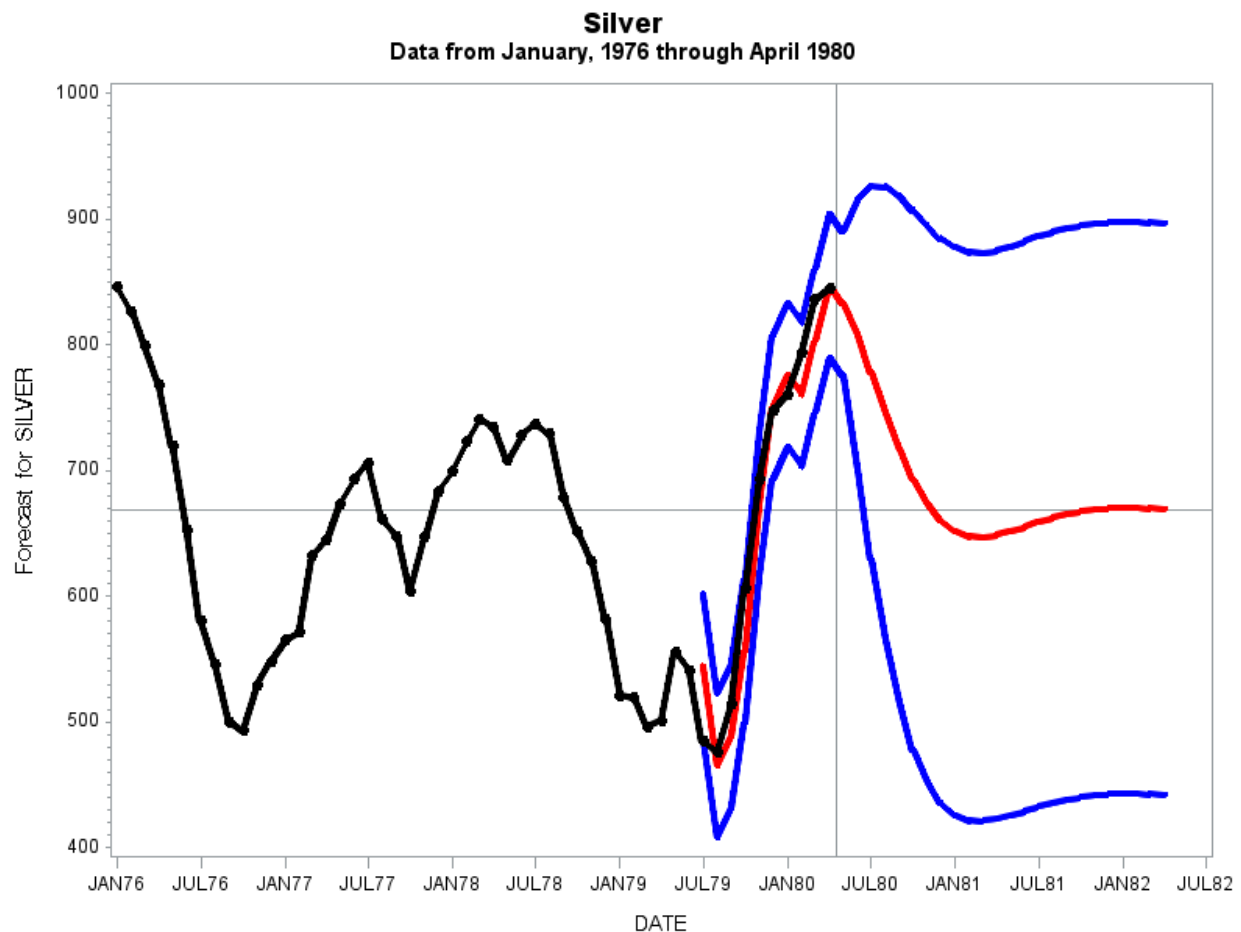

$$\hat{Y}_{t+2} = \mu + \alpha_1(\hat{Y}_{t+1} - \mu) + \alpha_2(Y_t - \mu), \quad \text{error} = e_{t+2} + \alpha_1 e_{t+1}$$

etc.

Prediction error variance ($\sigma^2 = \text{variance}(e_t)$)

$$\sigma^2, (1 + \alpha_1^2)\sigma^2, \dots$$

From prediction error variances, get 95% prediction intervals. Can estimate variance of e_t from past data. SAS PROC ARIMA does it all for you!

Moving Average, MA(q), and ARMA(p,q) models

$$\text{MA}(1) \quad Y_t = \mu + e_t - \theta e_{t-1} \quad \text{Variance } (1+\theta^2)\sigma^2$$

$$Y_{t-1} = \mu + e_{t-1} - \theta e_{t-2} \quad \rho(1) = -\theta/(1+\theta^2)$$

$$Y_{t-2} = \mu + e_{t-2} - \theta e_{t-3} \quad \rho(2) = 0/(1+\theta^2) = 0$$

Autocorrelation function “**ACF**” ($\rho(j)$) is 0 after lag q for MA(q). PACF is useless for identifying q in MA(q).

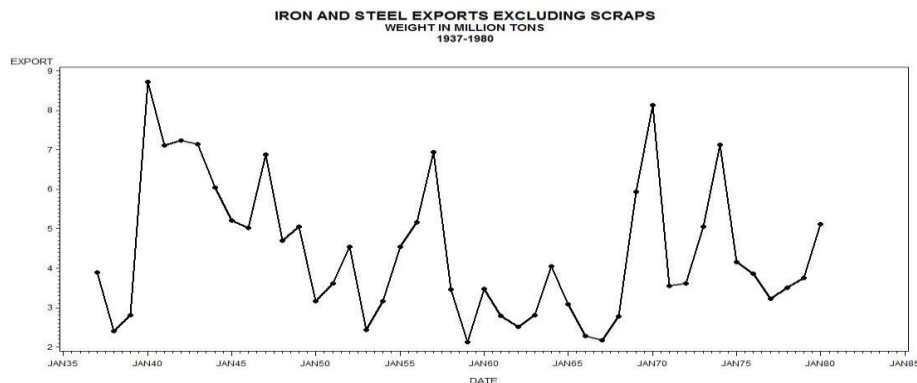

PACF drops to 0 after lag 3 \rightarrow AR(3) $p=3$

ACF drops to 0 after lag 2 \rightarrow MA(2) $q=2$

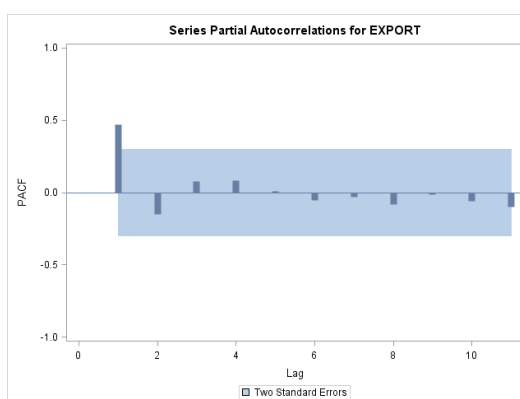

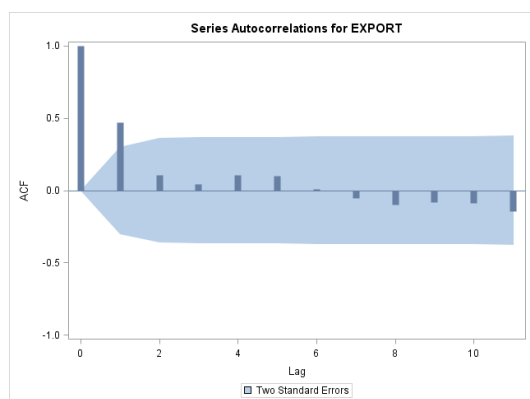

Neither drops \rightarrow ARMA(p,q) $p=$ ____ $q=$ ____

$$(Y_t - \mu) - \alpha_1(Y_{t-1} - \mu) - \dots - \alpha_p(Y_{t-p} - \mu) = e_t - \theta_1 e_{t-1} - \dots - \theta_q e_{t-q}$$

Example 2: Iron and Steel Exports.

```
PROC ARIMA plots(unpack)=all;
  Identify VAR=EXPORT;
```

ACF (could be MA(1))
Spike at lags 0, 1

PACF (could be AR(1))
No spike at lag 0

```
Estimate P=1 ML;
Estimate Q=2 ML;
Estimate Q=1 ML;
```

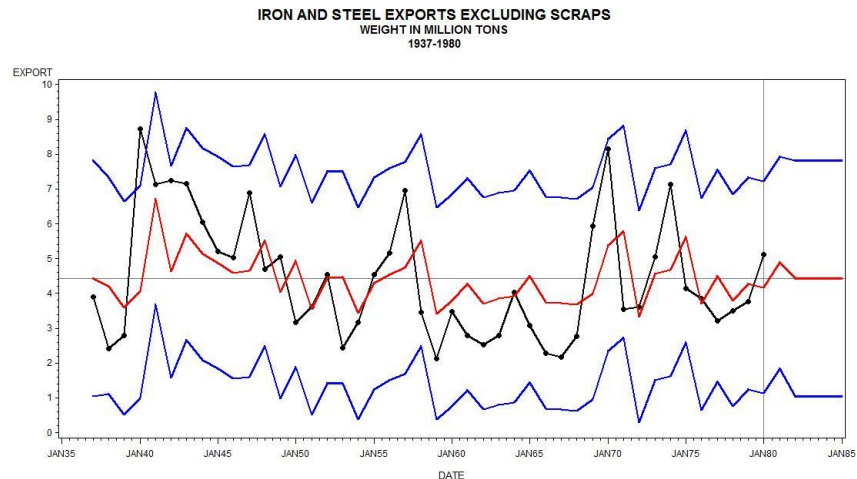

Maximum Likelihood Estimation

| Parameter | Estimate | t Value | Approx Pr> t | Lag |
|--------------|-----------------|--------------|------------------|----------|
| MU | 4.42129 | 10.28 | <.0001 | 0 |
| AR1,1 | 0.46415 | 3.42 | 0.0006 | 1 |

```

Conclusions for Brewers:

Both models have statistically significant parameters.

Both models are sufficient (no lack of fit)

Predictions from MA(1):

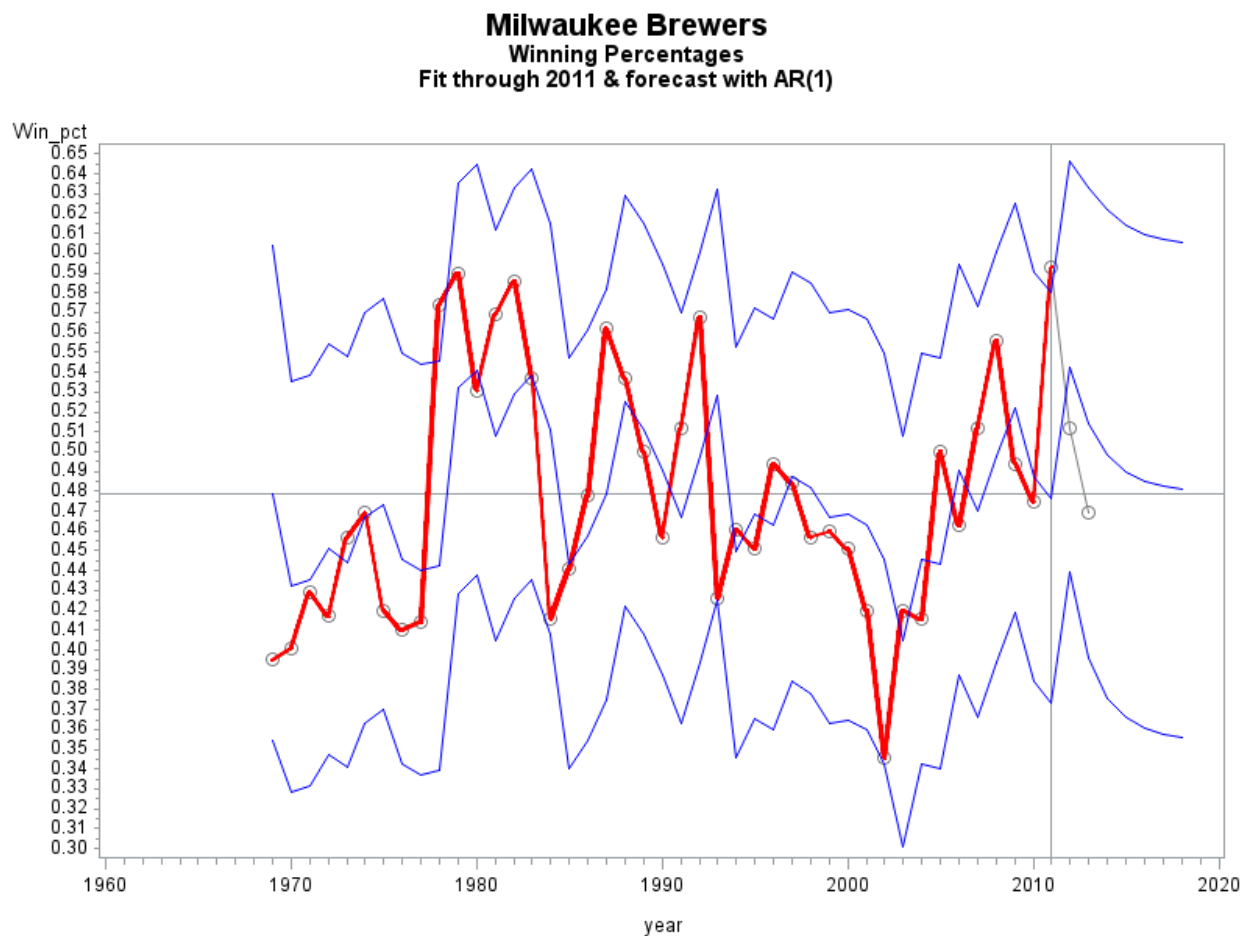

First one uses correlations

The rest are on the mean.

Predictions for AR(1):

Converge exponentially fast toward
mean

Not much difference but AIC prefers AR(1)

Stationarity

- (1) Mean constant (no trends)
- (2) Variance constant
- (3) Covariance $\gamma(j)$ and correlation

$$\rho(j) = \gamma(j)/\gamma(0)$$

between Y_t and Y_{t-j} depend only on j

ARMA(p,q) model

$$(Y_t - \mu) - \alpha_1(Y_{t-1} - \mu) - \dots - \alpha_p(Y_{t-p} - \mu) = e_t - \theta_1 e_{t-1} - \dots - \theta_q e_{t-q}$$

Stationarity guaranteed whenever solutions of equation (roots of polynomial)

$$X^p - \alpha_1 X^{p-1} - \alpha_2 X^{p-2} - \dots - \alpha_p = 0$$

are all < 1 in magnitude.

Examples

(1) $Y_t - \mu = .8(Y_{t-1} - \mu) + e_t$ $X - .8 = 0 \rightarrow X = .8$
stationary

(2) $Y_t - \mu = 1.00(Y_{t-1} - \mu) + e_t$ **nonstationary**

Note: $Y_t = Y_{t-1} + e_t$ Random walk

(3) $Y_t - \mu = 1.6(Y_{t-1} - \mu) - 0.6(Y_{t-2} - \mu) + e_t$

“characteristic polynomial”

$$X^2 - 1.6X + 0.6 = 0 \rightarrow \mathbf{X=1} \text{ or } X=0.6$$

nonstationary (unit root $X=1$)

$$(Y_t - \mu) - (Y_{t-1} - \mu) = 0.6[(Y_{t-1} - \mu) - (Y_{t-2} - \mu)] + e_t$$

$$(Y_t - Y_{t-1}) = 0.6(Y_{t-1} - Y_{t-2}) + e_t$$

First differences form stationary AR(1) process!

No mean – no mean reversion – no gravity pulling toward the mean.

$$(4) Y_t - \mu = 1.60(Y_{t-1} - \mu) - 0.63(Y_{t-1} - \mu) + e_t$$

$$X^2 - 1.60X + 0.63 = 0 \rightarrow X = 0.9 \text{ or } X = 0.7$$

$|\text{roots}| < 1 \rightarrow \text{stationary}$

$$(Y_t - \mu) - (Y_{t-1} - \mu) =$$

$$-0.03(Y_{t-1} - \mu) + 0.63[(Y_{t-1} - \mu) - (Y_{t-2} - \mu)] + e_t$$

$$Y_t - Y_{t-1} = -0.03(Y_{t-1} - \mu) + 0.63(Y_{t-1} - Y_{t-2}) + e_t$$

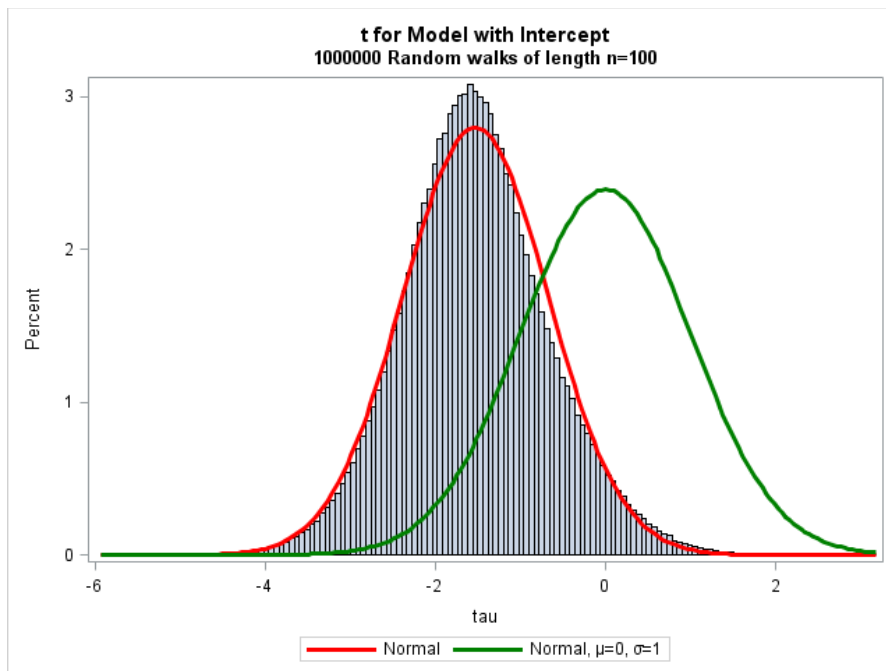

Unit Root testing (H_0 : Series has a unit root)

Regress

$$Y_t - Y_{t-1} \text{ on } Y_{t-1} \text{ and } (Y_{t-1} - Y_{t-2})$$

Look at t test for Y_{t-1} . If it is significantly negative then stationary.

Problem: Distribution of t stat is *not t distribution* under unit root hypothesis.
Distribution looks like this histogram:

Overlays: $N(\text{sample mean \& variance})$ $N(0,1)$

Correct distribution: Dickey-Fuller test in PROC ARIMA.

-2.89 is the correct (left) 5th %ile

46% of t's are less than -1.645

(the normal 5th percentile)

Example 1: Brewers

```
proc arima data=brewers;  
  identify var=Win_Pct nlag=12 stationarity=(ADF=0);
```

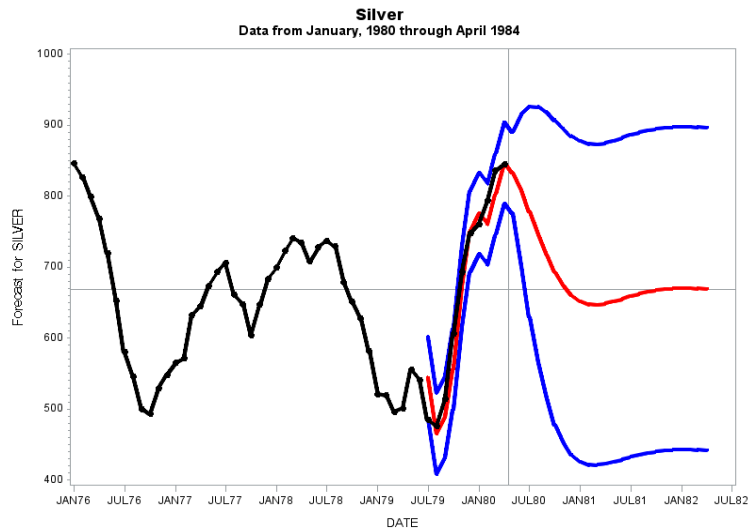

Dickey-Fuller Unit Root Tests

| Type | Lags | Rho | Pr < Rho | Tau | Pr < Tau |
|-------------|------|----------|----------|-------|----------|
| Zero Mean | 0 | -0.1803 | 0.6376 | -0.22 | 0.6002 |
| Single Mean | 0 | -21.0783 | 0.0039 | -3.75 | 0.0062 |
| Trend | 0 | -21.1020 | 0.0287 | -3.68 | 0.0347 |

Conclusion reject H_0 : unit roots so Brewers series is stationary (mean reverting).

0 lags \rightarrow do not need lagged differences in model (just regress $Y_t - Y_{t-1}$ on Y_{t-1})

Example 2: Stocks of silver revisited

Needed AR(2) (2 lags) so regress

$Y_t - Y_{t-1}$ (D_Silver) on

Y_{t-1} (L_Silver) and $Y_{t-1} - Y_{t-2}$ (D_Silver_1)

PROC REG:

Parameter Estimates

| Parameter | | | | |
|------------|----|----------|---------|------------------------|
| Variable | DF | Estimate | t Value | Pr> t |
| Intercept | 1 | 75.58073 | 2.76 | 0.0082 |
| L_Silver | 1 | -0.11703 | -2.78 | 0.0079 ☹️ wrong distn. |
| D_Silver_1 | 1 | 0.67115 | 6.21 | <.0001 😊 OK |

PROC ARIMA:

Augmented Dickey-Fuller Unit Root Tests

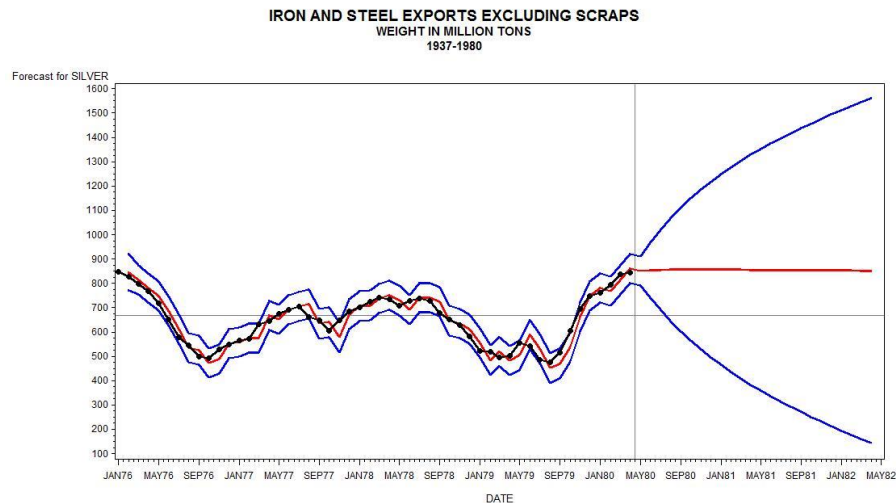

| Type | Lags | Rho | Pr<Rho | Tau | Pr<Tau | |
|-------------|------|----------|--------|--------------|---------------|------|
| Zero Mean | 1 | -0.2461 | 0.6232 | -0.28 | 0.5800 | |
| Single Mean | 1 | -17.7945 | 0.0121 | -2.78 | 0.0689 | 😊 OK |
| Trend | 1 | -15.1102 | 0.1383 | -2.63 | 0.2697 | |

Same t statistic, corrected p-value!

Conclusion: Unit root → difference the series.

1 lag → need 1 lagged difference in model
(regress $Y_t - Y_{t-1}$ on Y_{t-1} and $Y_{t-1} - Y_{t-2}$)

```
PROC ARIMA data=silver;  
  identify var=silver(1) stationarity=(ADF=(0));  
  estimate p=1 ml;  
  forecast lead=24 out=outN ID=date  
                    Interval=month;
```

Unit root forecast & forecast interval

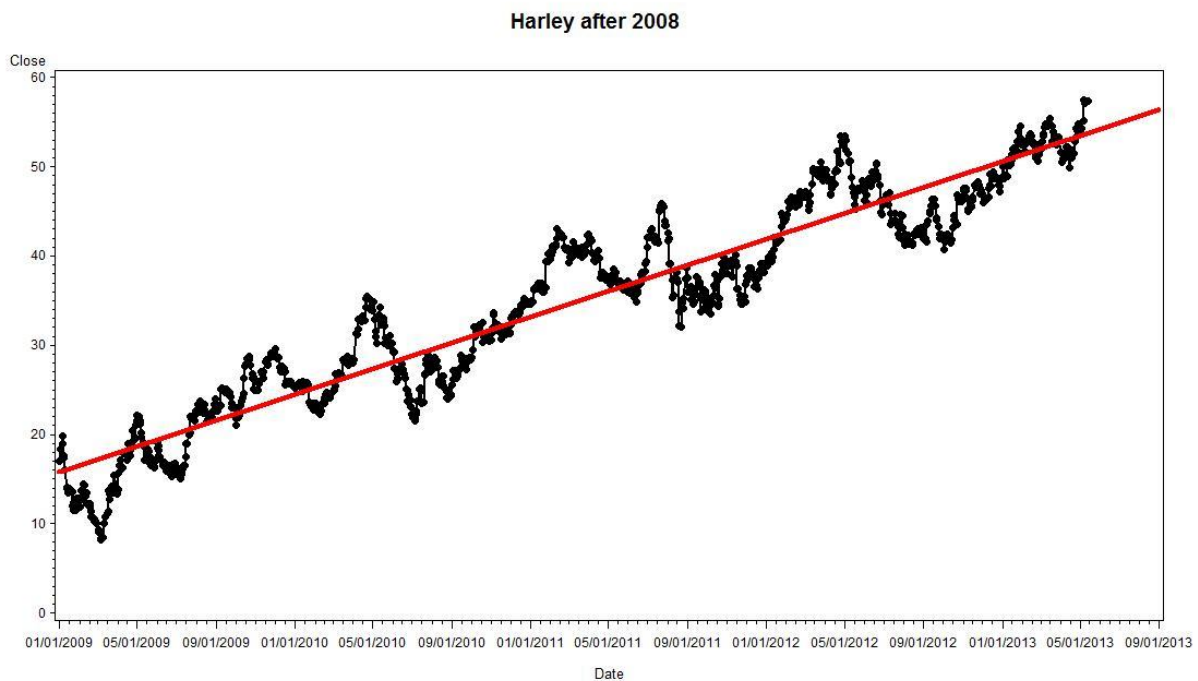

PROC AUTOREG

Fits a regression model (least squares)

Fits stationary autoregressive model to error terms

Refits accounting for autoregressive errors.

Example 3: **AUTOREG** Harley-Davidson
closing stock prices 2009-present.

```
proc autoreg data=Harley;
model close=date/ nlag=15 backstep;
run;
```

One by one, AUTOREG eliminates insignificant lags then:

| Estimates of Autoregressive Parameters | | | |
|--|-------------|----------------|---------|
| Lag | Coefficient | Standard Error | t Value |
| 1 | -0.975229 | 0.006566 | -148.53 |

Final model:

| Parameter Estimates | | | | | |
|---------------------|----|-----------|----------------|---------|-------------------|
| Variable | DF | Estimate | Standard Error | t Value | Approx Pr > t |
| Intercept | 1 | -412.1128 | 35.2646 | -11.69 | <.0001 |
| Date | 1 | 0.0239 | 0.001886 | 12.68 | <.0001 |

Error term Z_t satisfies $Z_t - 0.97Z_{t-1} = e_t$.

Example 3 **ARIMA**: Harley-Davidson closing stock prices 2009-present.

Apparent upward movement: Linear trend or nonstationary?

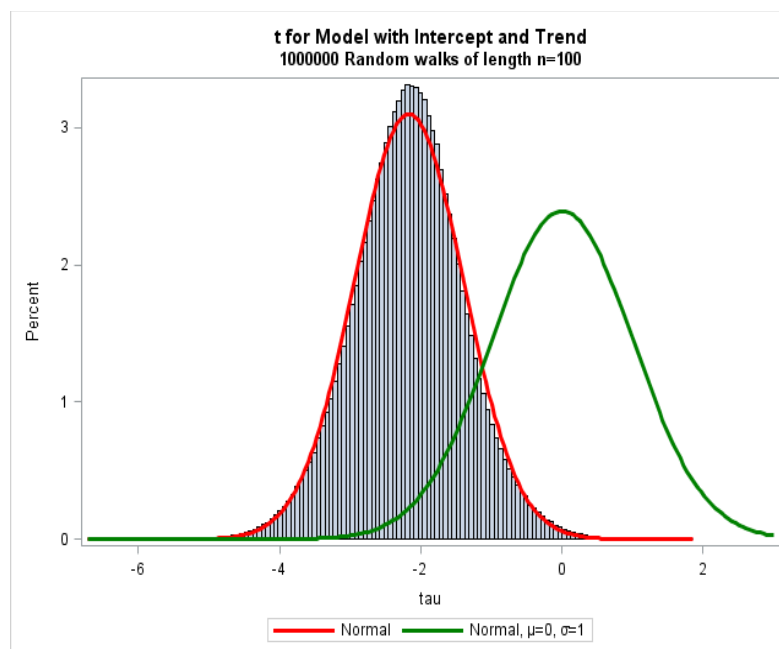

Regress

$Y_t - Y_{t-1}$ on 1, t , Y_{t-1} (& lagged differences)

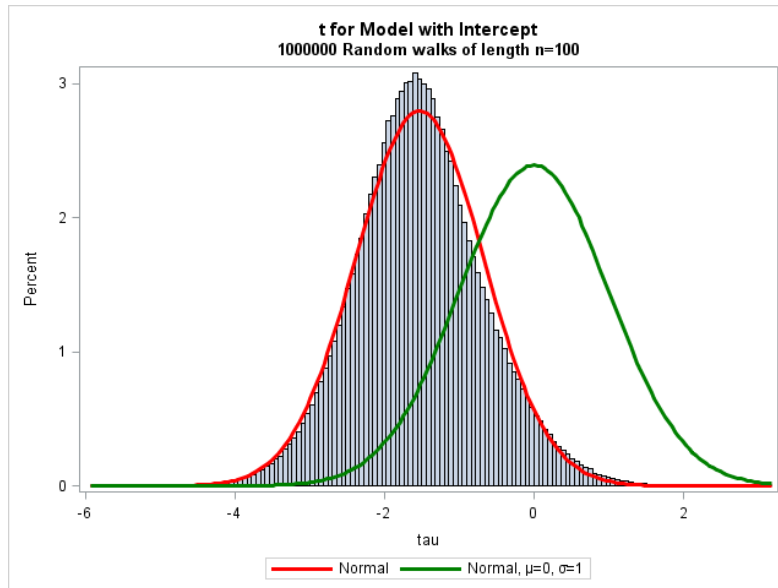

$H_0: Y_t = \beta + Y_{t-1} + e_t$ “random walk with drift”

$H_1: Y_t = \alpha + \beta t + Z_t$ with Z_t stationary

New distribution for Y_{t-1} t-test

With trend

Without trend

NCSU Energy Demand

Type of day

Class Days

Work Days (no classes)

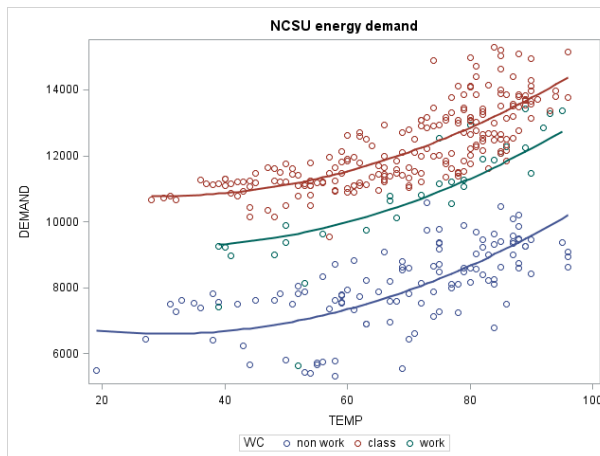

Holidays & weekends.

Temperature

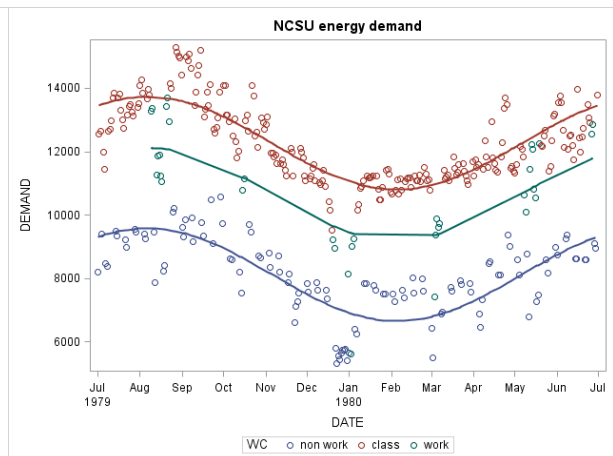

Season of Year

Step 1: Make some plots of energy demand vs. temperature and season. Use type of day as color.

Seasons: $S = A \sin(2\pi t/365)$, $C=B \sin(2\pi t/365)$

Temperature

Season of Year

Step 2: PROC AUTOREG with all inputs:

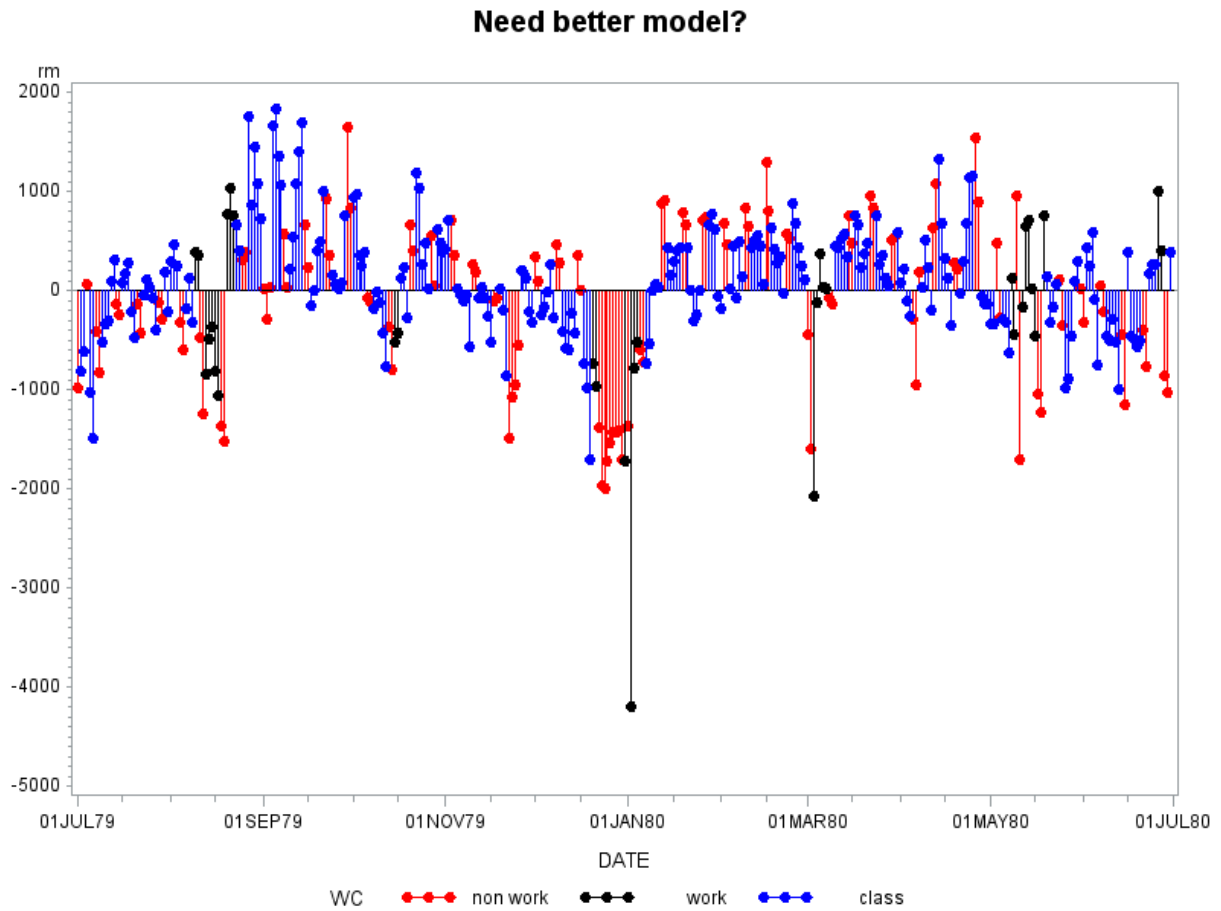

```
PROC AUTOREG data=energy;  
MODEL DEMAND = TEMP TEMPSQ CLASS WORK S C  
  /NLAG=15 BACKSTEP DWPROB;  
output out=out3  
  predicted = p predictedm=pm  
  residual=r residualm=rm;  
run;
```

| Estimates of Autoregressive Parameters | | | |
|--|-------------|----------------|---------|
| Lag | Coefficient | Standard Error | t Value |
| 1 | -0.559658 | 0.043993 | -12.72 |
| 5 | -0.117824 | 0.045998 | -2.56 |
| 7 | -0.220105 | 0.053999 | -4.08 |
| 8 | 0.188009 | 0.059577 | 3.16 |
| 9 | -0.108031 | 0.051219 | -2.11 |
| 12 | 0.110785 | 0.046068 | 2.40 |
| 14 | -0.094713 | 0.045942 | -2.06 |

Autocorrelation at 1, 7, 14, and others.

After autocorrelation adjustments, trust t tests etc.

| Parameter Estimates | | | | | |
|---------------------|----|-----------|----------------|---------|----------------|
| Variable | DF | Estimate | Standard Error | t Value | Approx Pr > t |
| Intercept | 1 | 6076 | 296.5261 | 20.49 | <.0001 |
| TEMP | 1 | 28.1581 | 3.6773 | 7.66 | <.0001 |
| TEMPSQ | 1 | 0.6592 | 0.1194 | 5.52 | <.0001 |
| CLASS | 1 | 1159 | 117.4507 | 9.87 | <.0001 |
| WORK | 1 | 2769 | 122.5721 | 22.59 | <.0001 |
| S | 1 | -764.0316 | 186.0912 | -4.11 | <.0001 |
| C | 1 | -520.8604 | 188.2783 | -2.77 | 0.0060 |

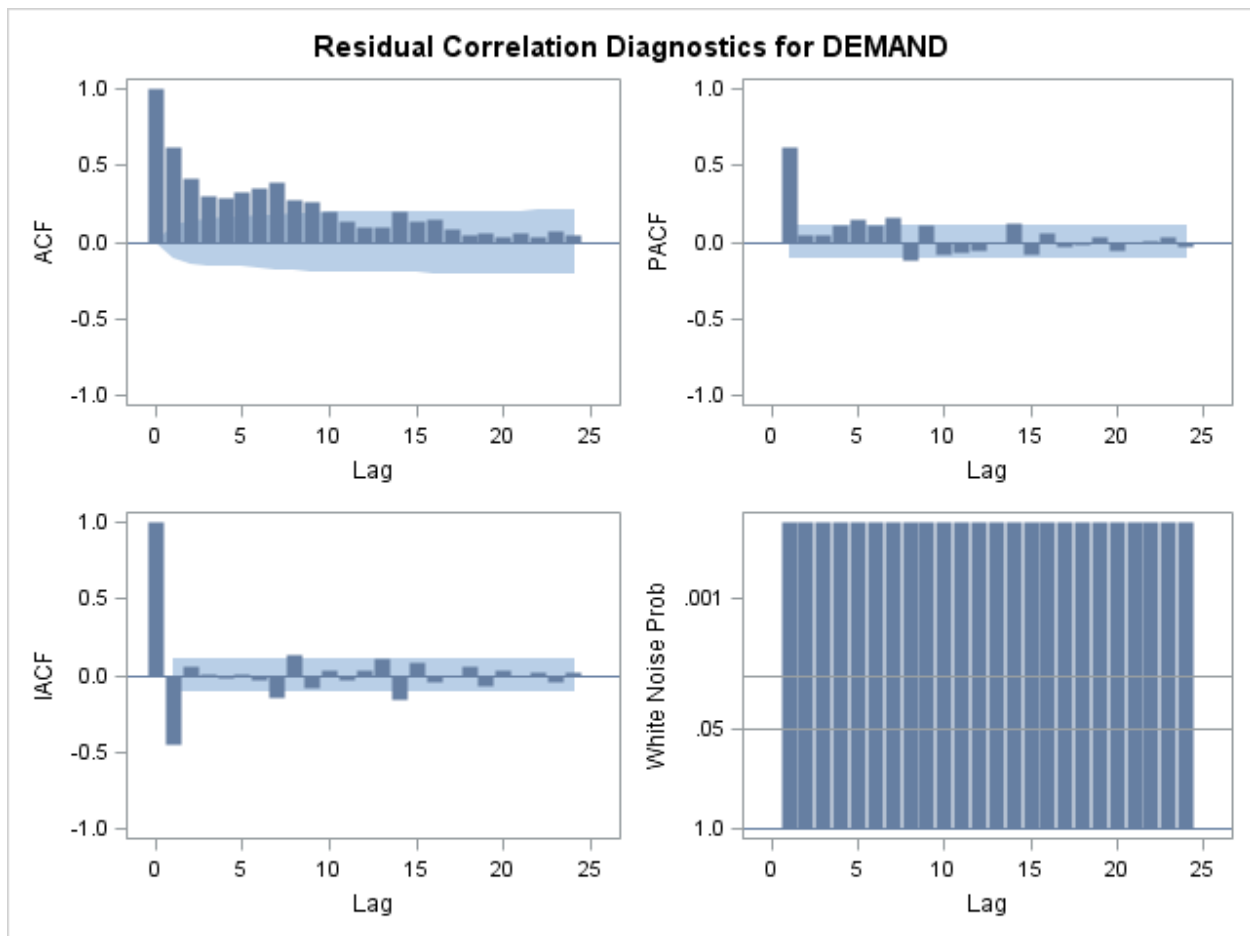

Residuals from regression part. Large residuals on workday near Christmas. Add dummy variable.

Same idea: PROC ARIMA

Step 1: Graphs

Step 2: Regress on inputs, diagnose residual autocorrelation:

Not white noise (bottom right)

Activity (bars) at lag 1, 7, 14

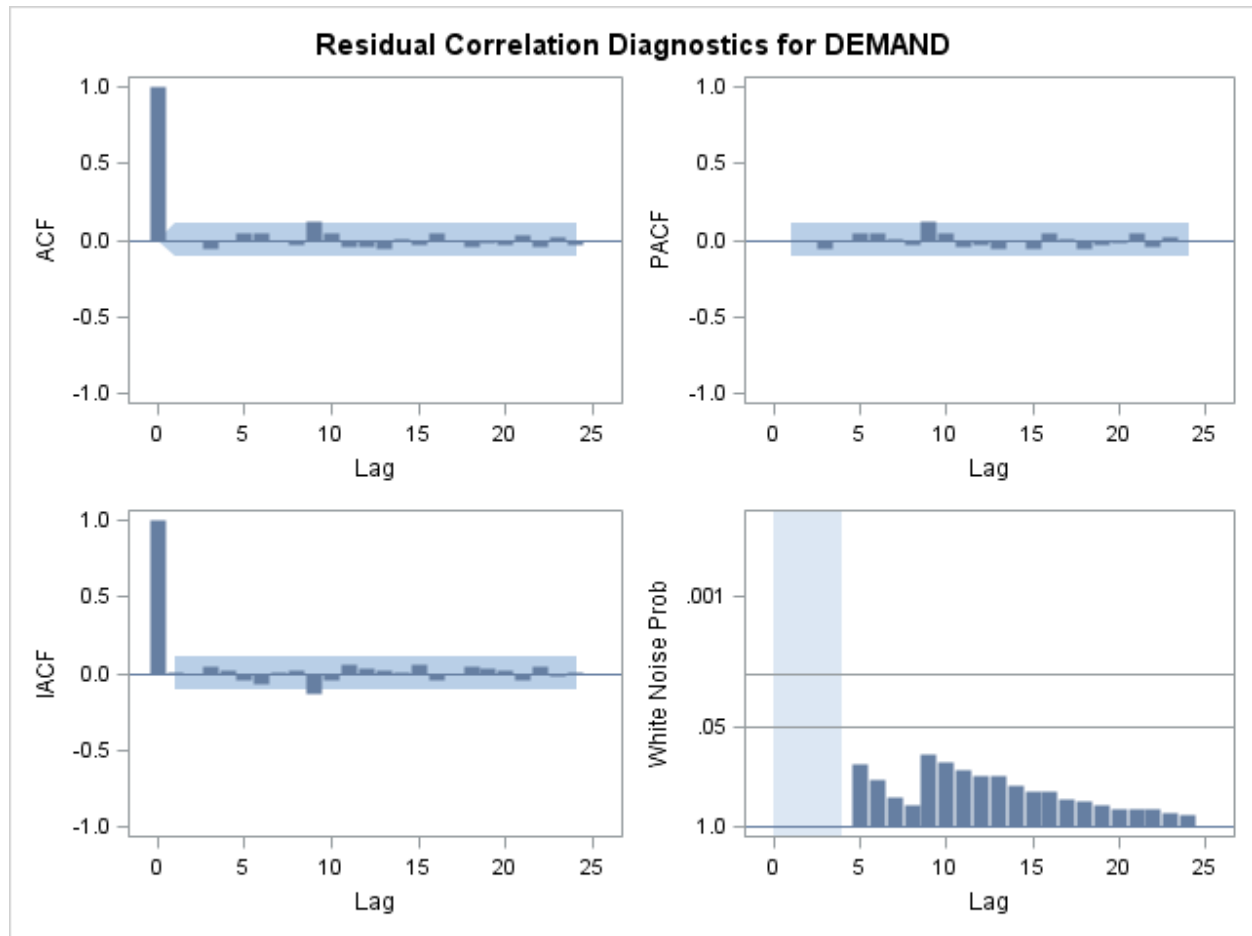

(3) Estimate resulting model from diagnostics plus trial and error:

```
e input = (temp tempsq class work s c) p=1
q=(1,7,14) ml;
```

| Maximum Likelihood Estimation | | | | | | | |
|-------------------------------|------------|----------------|---------|-------------------|-----|----------|-------|
| Parameter | Estimate | Standard Error | t Value | Approx Pr > t | Lag | Variable | Shift |
| MU | 6183.1 | 300.87297 | 20.55 | <.0001 | 0 | DEMAND | 0 |
| MA1,1 | 0.11481 | 0.07251 | 1.58 | 0.1133 | 1 | DEMAND | 0 |
| MA1,2 | -0.18467 | 0.05415 | -3.41 | 0.0006 | 7 | DEMAND | 0 |
| MA1,3 | -0.13326 | 0.05358 | -2.49 | 0.0129 | 14 | DEMAND | 0 |
| AR1,1 | 0.73980 | 0.05090 | 14.53 | <.0001 | 1 | DEMAND | 0 |
| NUM1 | 26.89511 | 3.83769 | 7.01 | <.0001 | 0 | TEMP | 0 |

| 48 | 43.35 | 44 | 0.4995 | -0.043 | 0.043 | -0.027 | -0.047 | -0.019 | -0.032 | |

Looking for “outliers” *that can be explained*

```
* 0.05/365 = .0001369863 (Bonferroni) *;  
outlier type=additive alpha=.0001369863 id=date;  
format date weekdate. ;  
run;
```

```
/******  
January 2, 1980 Wednesday: Hangover Day :-) .
```

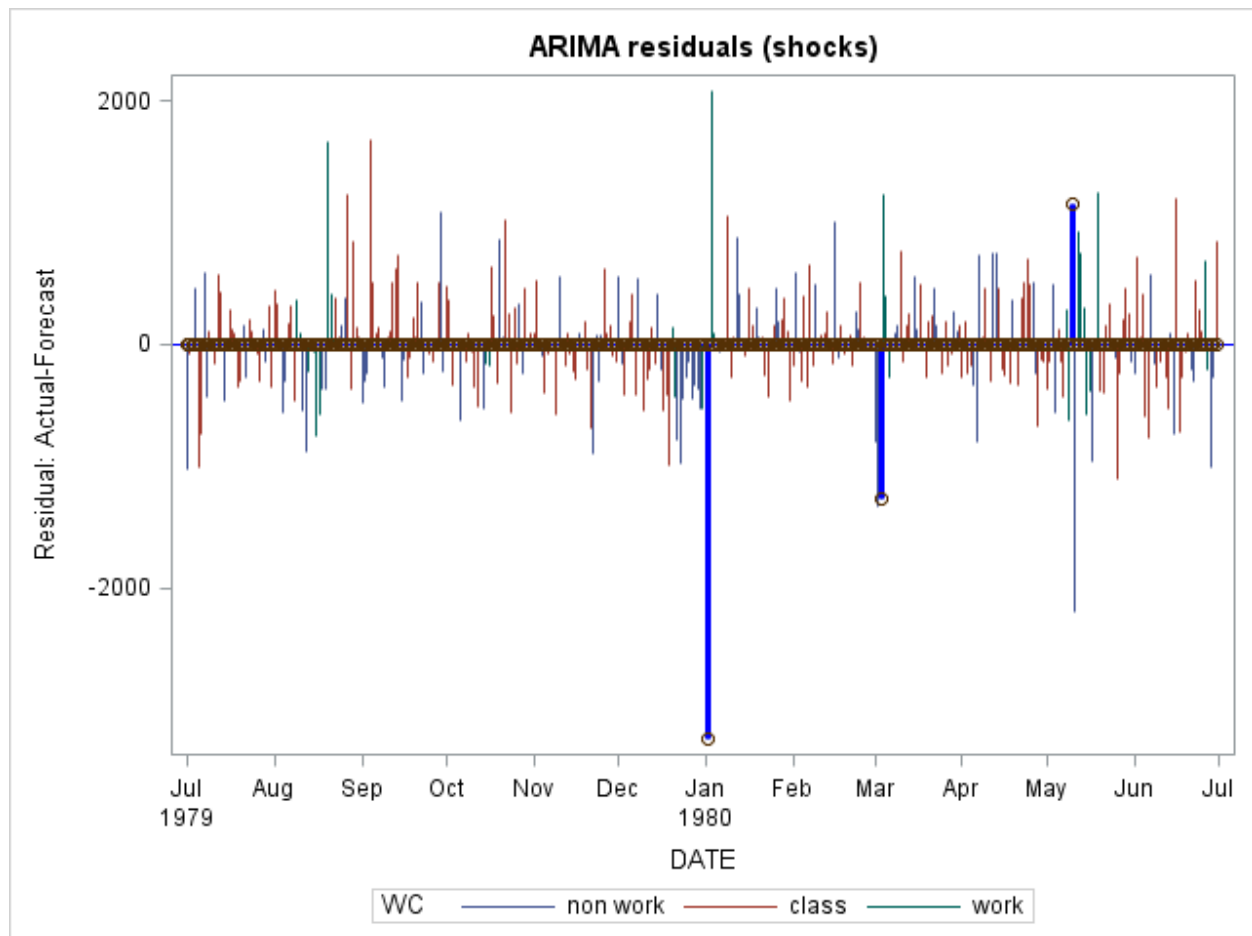

March 3, 1980 Monday:

On the afternoon and evening of March 2, 1980, North Carolina experienced a major winter storm with heavy snow across the entire state and near blizzard conditions in the eastern part of the state. Widespread snowfall totals of 12 to 18 inches were observed over Eastern North Carolina, with localized amounts ranging up to 22 inches at Morehead City and 25 inches at Elizabeth City, with unofficial reports of up to 30 inches at Emerald Isle and Cherry Point (Figure 1). This was one of the great snowstorms in Eastern North Carolina history. What made this storm so remarkable was the combination of snow, high winds, and very cold temperatures.

```
May 10, 1980 Saturday: Last day of Spring semester.  
*****/;
```

| Outlier Details | | | | | |
|-----------------|-----------|----------|----------|------------|-------------------|
| Obs | Time ID | Type | Estimate | Chi-Square | Approx Prob>ChiSq |
| 186 | Wednesday | Additive | -3250.9 | 87.76 | <.0001 |
